August 2021
Let \((X, \mathcal{B}, \mu)\) be a probability space and \(\tau : X \rightarrow X\) be a measurable transformation.

**Definition**

Measure \(\mu\) is said to be \(\tau\)-invariant if and only if for every \(E \in \mathcal{B}\),

\[
\mu(\tau^{-1}E) = \mu(E).
\]

Alternatively, we may say that \(\tau\) is a measure-preserving transformation.

**Definition**

Measure-preserving transformation \(\tau\) is ergodic if for every \(E \in \mathcal{B}\) with \(\tau^{-1}E = E\), either \(\mu(E) = 0\) or \(\mu(E) = 1\).
**Theorem (Birkhoff’s Ergodic Theorem)**

Let \((X, \mathcal{B}, \mu)\) be a measure space, \(\tau\) an ergodic transformation and suppose \(g\) is a \(\mu\)-integrable function, then

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} g(\tau^i(x)) = \frac{1}{\mu(X)} \int_X g \, d\mu \quad \text{a.e.}
\]

**Corollary**

Let \((X, \mathcal{B}, \mu)\) be a probability space and \(\tau\) an ergodic transformation, then

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=0}^{n-1} \chi_E(\tau^i(x)) = \mu(E) \quad \mu - \text{a.e.}
\]
Baker’s Map

Consider the (folded) baker’s map given by

$$\tau(x, y) = \begin{cases} 
(2x, y/2), & 0 \leq x \leq 1/2 \\
(2 - 2x, 1 - y/2), & 1/2 < x \leq 1 
\end{cases}$$

This transformation preserves two-dimensional lebesgue measure.
Density Functions

If $\mu$ is absolutely continuous with respect to Lebesgue measure $\lambda$ (the usual notion of length/area/volume), then we can write

$$\mu(E) = \int_E f \, d\lambda,$$

for some function $f$.

We refer to $f$ as the density of $\mu$.

Definition

The Frobenius-Perron operator $P_\tau$ is defined by

$$\int_E P_\tau f \, d\lambda = \int_{\tau^{-1}E} f \, d\lambda.$$

If $P_\tau f = f$, then the measure $\mu$ defined by $f$ is invariant.
Methods

Histogram

Direct application of Birkhoff’s Ergodic theorem. Partition the interval into ”bins” $E_i$. For each bin, calculate

$$\frac{1}{N} \sum_{i=0}^{N-1} \chi_{E_i}(\tau^i(x)) = \mu(E_i),$$

for large integer $N$.

Ulam’s method

Uses a finite approximation of the Frobenius-Perron operator. Divide interval into $n$ equal subintervals $I_1, I_2, \ldots, I_n$ and define

$$P_{ij} = \frac{\lambda(I_i \cap \tau^{-1}I_j)}{\lambda(I_i)},$$

and

$$P_n \chi_i = \sum_{j=1}^{n} P_{ij} \chi_j.$$

Find fixed point $f_n$ of $P_n$. 
B-splines

**Nodes**

Begin by generating the following $n + 1$ nodes

$$a_{-1} < a_0 < \ldots < a_{n-2} < a_{n-1}, \text{ where } a_i = i/n.$$  

**2D Linear B-splines**

Define

$$L(x) = \begin{cases} 
  x, & 0 \leq x \leq 1 \\
  2 - x, & 1 < x \leq 2 \\
  0, & x \notin [0, 2]
\end{cases}$$

Generate the following $(n + 1)^2$ linear B-splines

$$B_{i,j}(x, y) = L \left( \frac{x - a_i}{1/n} \right) L \left( \frac{y - a_j}{1/n} \right), \quad i, j \in \{-1, 0, \ldots, n-1\}$$
B-Splines

(a) B-splines for $n = 4$

(b) B-splines restricted to $[0, 1]^2$
Maximum Entropy

**Definition (Boltzmann Entropy)**

The **Boltzmann entropy** $H$ of a nonnegative integrable function $f$ is defined to be

$$H(f) = -\int_{[0,1]^k} f(\vec{x}) \ln f(\vec{x}) \, d\vec{x}$$

Our constrained maximization problem is of the following form

$$\max \left\{ H(f) : \|f\| = 1, \int_0^1 \int_0^1 f(x, y) B_i(x, y) \, dxdy = m_i \right\}$$

To which our solution is of the form

$$f_n(x, y) = e^{\sum_{i=1}^{(n+1)^2} c_i B_i(x, y)}$$
1. Choose $n$ and partition $[0, 1]^2$ into $n^2$ sets

2. Approximate moments $m_i$ using

$$m_i \approx \frac{1}{N} \sum_{j=0}^{N-1} B_i(\tau^j(x, y)), \quad i = 1, 2, \ldots, (n + 1)^2$$

for some large $N$ and some $x, y \in [0, 1]$

3. Solve the following system for $c_1, c_2, \ldots, c_{(n+1)^2}$

$$\int_0^1 \int_0^1 B_i(x, y) e^{\sum_{j=1}^{(n+1)^2} c_j B_j(x, y)} \, dx \, dy = m_i, \quad i = 1, 2, \ldots, (n+1)^2$$

4. Form density $f_n(x, y) = e^{\sum_{i=1}^{(n+1)^2} c_i B_i(x, y)}$
Consider the transformation given by \( \tau(x, y) = (S(x), T(y)) \), where

\[
S(x) = \left( \frac{1}{8} - 2 \left| x - \frac{1}{2} \right|^3 \right)^{1/3} + 1/2,
\]

\[
T(y) = \begin{cases} 
\frac{2y}{1-y^2}, & 0 \leq y < \sqrt{2} - 1 \\
\frac{1-y^2}{2y}, & \sqrt{2} - 1 \leq y \leq 1
\end{cases}
\]

The exact density is given by

\[
f^*(x, y) = \frac{48(x - 1/2)^2}{\pi(1 + y^2)}.
\]

Concluding Remarks

The linear spline maximum entropy method described for multidimensional transformations is easy to implement but can suffer from a few problems. Namely, the use of Birkhoff’s ergodic theorem means there is the possibility of choosing an initial point that does not obey the desired relationship between time average and space average. There is also the concern of how the approximation of the moments will affect the approximation of our density. Much of the computational cost of this algorithm comes from the solution of the system using some system solver such as Newton’s method.
